# **TechTalk**

## Project Report

https://github.com/PalAsmita/TechTalk.git

Blazer IDs Asmita Pal – apal Bhavya Bindu Arrpula – barrpula

#### Introduction:

The project involves creating a Flask application for checking password formats and managing user sign-ups and logins using an SQLite database.

### Technologies:

- Flask: Used to create a web application framework for the password checker and user management system.
- SQLite: Employed as the database for storing user data.
- Visual Studio Code (VSCode): The integrated development environment (IDE) used for code editing and database management.
- -Anaconda
- HTML and Bootstrap

## Results:

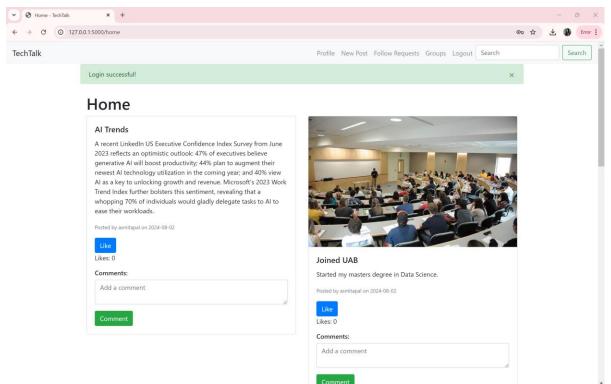

### Login

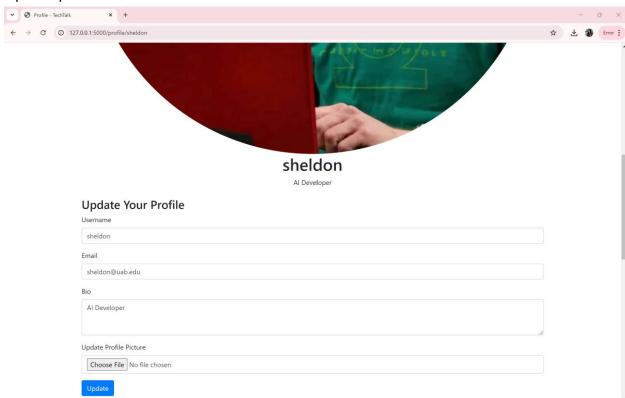

# Register

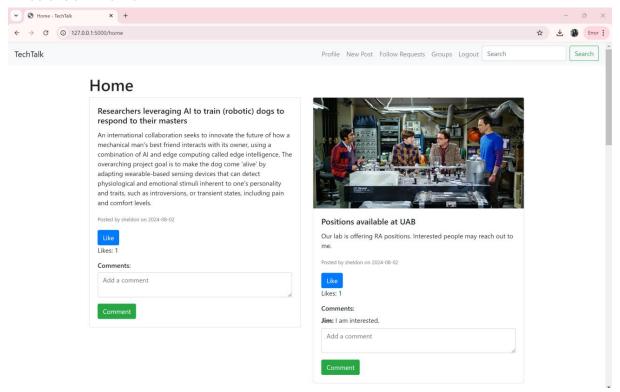

#### Home

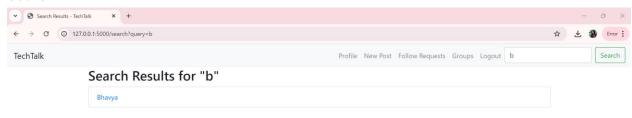

# Update profile

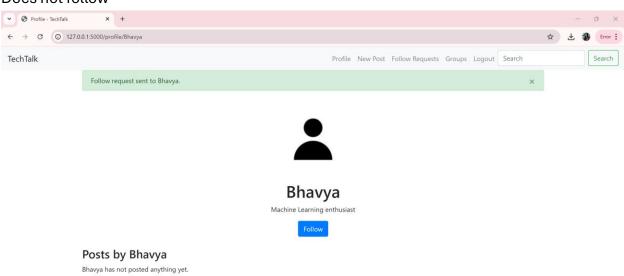

### Likes & Comments

### Search

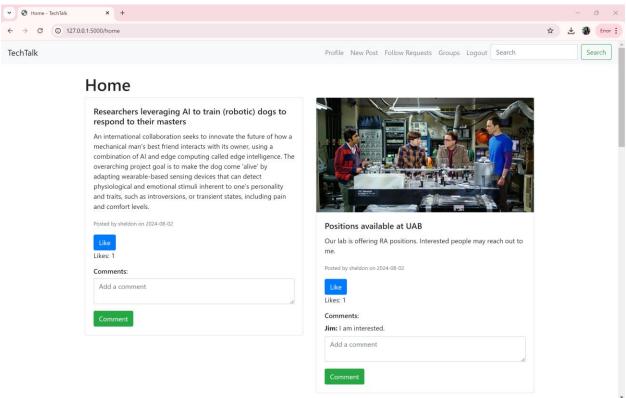

### Does not follow

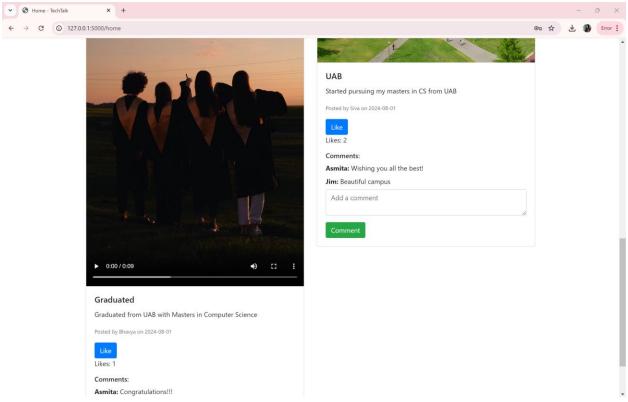

## Follow request

## After accepting request

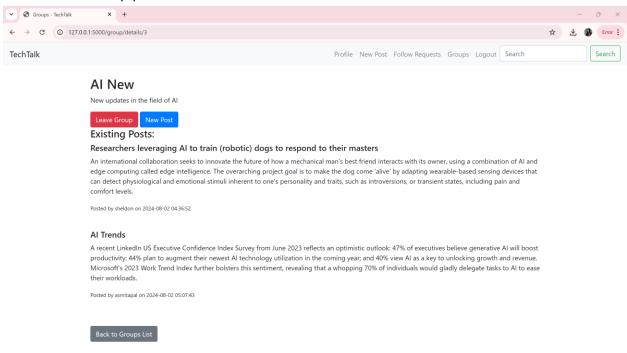

Images and video posts

# List of all groups

### Create new Group posts

### **Features**

- Flask Application:
- Implemented a password checker that verifies passwords meet specific criteria (uppercase letter, lowercase letter, a number, and minimum 6 characters long).
- Developed a user sign-up and login system with password validation and email uniqueness checks.
- Configured SQLite with Flask for database management.
- Users can create profiles, enter bio information, and upload profile pictures
- Users can search and find other accounts using a search feature.
- Users can send follow requests to other users and can accept or decline follow requests.
- Users can share posts that can include text, images, and videos. Posts should be visible to the followers of the user who posted them.
- Followers can like posts. Followers can comment on posts. The number of likes and comments should be visible on each post.
- Users can create groups related to specific topics or interests. Users can join existing groups. Users can share posts within the groups they are part of. Posts shared in groups should be visible to all group members.

#### Discussions:

The project faced some challenges, when the database got deleted accidentally but the data was still stored. So, it was unable to run as the migration folder did not have the correct files and the .env file was corrupted. Finally, we had to create a new\_database. Also, migrating any changes to the database. We also faced an issue with the follow button. If someone requested to follow, once the requested was accepted, one person was following the other person, but the second person was unable to see any posts from them, and it didn't say they followed them. Other important aspects were ensuring the correct extension installation, handling file permissions, and dealing with potential file locking or corruption. These issues were addressed by verifying the installation of the SQLite extension, checking file paths and permissions, and ensuring the database was not in use by other applications.
